AMALGAMS OF SYMMETRIC GROUPS AND $\mathfrak{H}_n$-EXTENSIONS

SERGEY SINCHUK

ABSTRACT. By amalgamating copies of symmetric group S_n we construct a central extension $S_n(G)$ of a large subgroup of the wreath product $G \wr S_n$. We then establish a connection between this group and the theory of $\mathfrak{U}(G)$ and $\mathfrak{H}_n(G)$-extensions developed by K. Dennis and U. Rehmann in 1970's. We also give a topological application of this construction by describing homotopy invariants of blah-blah-blah...

1. INTRODUCTION

The aim of this note is to establish a surprising connection between symmetric groups and (certain quotients of) nonabelian tensors squares.

Let G be a group. Denote by $D_n(G)$ the subgroup of G^n consisting of vectors $(g_1, \ldots, g_n)$ for which the product $g_1 \cdot \ldots \cdot g_n$ lies in the derived subgroup $[G, G]$. Recall from Rehmann's paper [11] that the universal *extension of type* $\mathfrak{H}_n$ (denoted $H_n(G)$) is, by definition, a certain (central) extension of $D_n(G)$ explicitly presented by generators and relations (see section 3 below). The extension $H_n(G)$ and its "antisymmetrization" $H_n^\wedge(G)$ can be characterised by the property that they fit into the following pullback squares:

$$
\begin{array}{ccc}
G \,\widetilde{\wedge}\, G & \longrightarrow\!\!\!\!\!\to & [G, G] \\
\cup\lrcorner\,\big\uparrow & & \big\uparrow{\scriptstyle\iota_1} \\
\big\downarrow & & \big\downarrow \\
H_n(G) & \longrightarrow & D_n(G)
\end{array}
\qquad
\begin{array}{ccc}
G \wedge G & \longrightarrow\!\!\!\!\!\to & [G, G] \\
\cup\lrcorner\,\big\uparrow & & \big\uparrow{\scriptstyle\iota_1} \\
\big\downarrow & & \big\downarrow \\
H_n^\wedge(G) & \longrightarrow & D_n(G)
\end{array}
$$

Here $G \wedge G$ denotes the nonabelian exterior square of G and $G \,\widetilde{\wedge}\, G$ is the modern notation for the Dennis group (G, G) defined in [4] (also denoted U_G by Rehmann in [11]). The map ι_1 in the above diagrams is defined by $\iota_1(g) = (g, 1, \ldots, 1)$.

Consider the family of copies of the symmetric group S_n where each copy is indexed by an n-tuple $(g_1, \ldots, g_n) \in G^n$. Denote by $S_n(G)$ the free product of groups from this family amalgamated over single family of relations of the form $s_g = s_h$, where

$s \in S_n$, $g, h \in G^n$ are such that hg^{-1} is fixed by the natural action of S_n on G^n (here we denote by s_g a permutation s embedded into the copy with index g).

Our first main result is the following theorem.

Theorem 1. *The group $S_n(G)$ is isomorphic to $S_n \ltimes H_n^\wedge(G)$.*

The proof of Theorem 1 proceeds as follows: The presentation of Theorem is similar in spirit (albeit simpler) than the presentation

Unsurprisingly, the presentation from Theorem 1 is obtained via van Kampen theorem and was discovered during the attempt to answer some purely topological question, which we describe in detail below.

For a pointed simplicial set (X, x_0) one denotes by $\mathbb{Z}[X]$ the associated free simplicial abelian group. Define the "alternating" map of simplicial sets $h_n \colon X^{2n} \to \mathbb{Z}[X]$ by the identity:

$$h_n(x_1, x_2, \ldots x_{2n}) = \sum_{i=1}^{2n} (-1)^i x_i.$$

Denote by X^∞ the colimit of X^n with respect to the natural embeddings $X^n \hookrightarrow X^{n+1}$ Taking colimit of h_n we get the map $h_\infty = \mathrm{colim}_n(h_n) \colon X^\infty \to \mathbb{Z}[X]$.

Based on a recent result of S. Podkorytov one can deduce that this map is a quasifibration provided X is fibrant and connected. In particular, the natural map $h_\infty^{-1}(0) \to F_{h_\infty}$ between the fiber and the homotopy fiber of h_∞ over 0 is a weak equivalence, see Lemma A.4.

Theorem 2. *If $X = BG$ is the classifying space of a group G then for $n \geq 3$ the natural map $h_n^{-1}(0) \to F_{h_n}$ induces an isomorphism of fundamental groups $\pi_1(h_n^{-1}(0)) \cong \pi_1(F_{h_n})$.*

The proof of Theorem 2 goes as follows. ???

In the course of the proof we also find a presentation of the universal $\mathfrak{H}_n(G)$-extension that is simpler than the original presentation introduced by Rehmann in [11], see Proposition 3.1.

1.1. **Acknowledgements.** I wish to thank S. Podkorytov for suggesting the problem and also for his kind permission to use some of his unpublished results. I am also grateful to S. O. Ivanov and V. Isaev for their numerous helpful comments and interest in this work.

2. The extension $S_n(G)$

2.1. **The definition of $S_n(G)$.** Let G be a group. Recall that the *wreath product* is, by definition, the semidirect product $G^n \rtimes S_n$, in which S_n acts on G^n on the right by permuting its factors.

Consider the family $\{S_n{}^{(g)}\}_{g \in G^n}$ of isomorphic copies of S_n indexed by elements of G^n and let F be the free product of groups from this family. For $s \in S_n$ and $g \in G^n$ we denote by s_g the image of s in F under the canonical map $S_n^{(g)} \to F$.

Definition 2.1. We define the group $S_n(G)$ to be the quotient of F modulo the following single family of relations:

{eq:main_rel}

$$(2.1) \qquad\qquad s_g = s_h, \text{ where } s \text{ fixes } hg^{-1}.$$

We continue to denote by s_g the image of the element $s_g \in F$ under the canonical map $F \to S_n(G)$.

Remark 2.2. Expanding the definition of the semidirect product we get that

$$s^g = (1_{G^n}, s)^{(g,1)} = (g^{-1}, s)(g, 1) = (g^{-1}g^{(s^{-1})}, s).$$

therefore the equality $s^g = s^h$ holds in $G \wr S_n$ iff $g^{-1}g^{(s^{-1})} = h^{-1}h^{(s^{-1})}$, or what is the same, iff s fixes hg^{-1}.

The last statement immediately implies that the map $\mu \colon S_n(G) \to G \wr S_n$ given by $\mu(s_g) = s^g = (g^{-1}g^{(s^{-1})}, s)$ is well-defined. We will see shortly that μ is, in fact, a *crossed module* in the sense of [2, § 2.2].

Observe from the definition of $S_n(G)$ that there is a split exact sequence.

{eq:ex-seq}

$$(2.2) \qquad\qquad 1 \longrightarrow \operatorname{Ker}(\pi) \longrightarrow S_n(G) \underset{\iota(1)}{\overset{\pi}{\rightleftarrows}} S_n \longrightarrow 1,$$

Here the map $\pi = \pi_{S_n} \circ \mu$ removes subscript g from each s_g and the section $\iota(1)$ sends s to s_1, where 1 is the identity element of G^n. Thus, if we denote $\operatorname{Ker}(\pi)$ by $HS_n(G)$ we get a decomposition $S_n(G) = HS_n(G) \rtimes S_n$.

2.2. **A crossed module structure on** $S_n(G)$**.** Recall from [2, § 2.2] that a *crossed module* is a morphism of groups $\mu \colon M \to N$ together with a right action of N on M compatible with the conjugation action of N on itself, i.e.

{eq:precrossed}

$$(\text{CM1}) \qquad\qquad \mu(m^n) = \mu(m)^n \text{ for all } n \in N, \, m \in M,$$

which also satisfies the following identity called *Peiffer identity*:

{eq:Peiffer}

$$(\text{CM2}) \qquad\qquad m^{m'} = m^{\mu(m')} \text{ for all } m, m' \in M.$$

In our situation, we let $G \wr S_n$ act on $S_n(G)$ by

{eq:action}

$$(2.3) \qquad\qquad (s_g)^{(h,t)} = s^t{}_{(gh)^t}, \text{ for } s, t \in S_n \text{ and } g, h \in G^n.$$

The goal of this subsection is to prove the following.

thm:cms

Proposition 2.3. *For $n \geq 3$ the map $\mu \colon S_n(G) \to G \wr S_n$ is a crossed module.*

From the fact that μ is a crossed module one can deduce that $\mathrm{Ker}(\mu)$ is a central subgroup of $S_n(G)$ and $\mathrm{Im}(\mu)$ is a normal subgroup of $G \wr S_n$. It is not hard to show that the group $S_2(G)$ is isomorphic to a free product of copies of S_2 (whose center is always trivial). Therefore, the requirement $n \geq 3$ in the statement of Proposition 2.3 is essential.

Verification of the fact that formula (2.3) gives a well-defined action of $G \wr S_n$ on $S_n(G)$ that satisfies (CM1) is lengthy but straightforward. Let us show that (CM2) holds. It suffices to verify Peiffer identities only for the generators of $S_n(G)$, for which it takes the form:

$$(2.4) \qquad t_h^{-1} s_g t_h = s^t_{(gh^{-1})^t \cdot h} \text{ for all } s, t \in S_n, \; g, h \in G^n.$$

If we act on both sides of the above formula by $(h^{-1}, 1) \in G \wr S_n$ we obtain the equality $t_1^{-1} s_{gh^{-1}} t_1 = s^t_{(gh^{-1})^t}$. Thus, to prove (2.4) it suffices to show the following simpler relation:

$$(2.5) \qquad t_1^{-1} s_g t_1 = s^t_{g^t} \text{ for all } s, t \in S_n, \; g \in G^n.$$

The key step in the proof is the following lemma.

Lemma 2.4. *The relation* (2.5) *holds in the special case when* $s = (ij)$ *and* $t = (kl)$ *are two nonequal transpositions.*

Proof. First of all, we immediately check that (2.5) holds in the special case when t fixes $g' \in G^n$. Indeed, by (2.1) we have $t_1 = t_{g'}$, hence

$$t_1^{-1} s_{g'} t_1 = t_{g'}^{-1} s_{g'} t_{g'} = (s^t)_{g'} = (s^t)_{g'^t}.$$

Without loss of generality we may assume that $l \neq i$ and $l \neq j$. Denote by g' the vector which differs from g only at l-th position, for which we set $g'_l = g_k$. Since the only nontrivial component of $g'g^{-1}$ (resp. $g'g^{-t}$) is located at l-th (resp. k-th) position, it is fixed by s (resp. s^t), hence from (2.1) we conclude that $s_g = s_{g'}$ (resp. $(s^t)_{g'} = (s^t)_{g^t}$). Finally, since g' is fixed by t, we get that

$$t_1^{-1} s_g t_1 = t_1^{-1} s_{g'} t_1 = (s^t)_{g'^t} = s^t_{g'} = (s^t)_{g^t}. \quad \square$$

Proof of Proposition 2.3. Let us show that (2.5) holds for arbitrary transpositions $s, t \in S_n$. It suffices to consider the case $s = t = (ij)$. After choosing some $k \neq i, j$ and presenting (ij) as $(kj)(ik)(kj)$ we use the lemma:

$$(ij)_1^{-1}(ij)_g(ij)_1 = (ij)_1^{-1}(kj)_g(ik)_g(kj)_g(ij)_1 = (ki)_{g^{(ij)}}(jk)_{g^{(ij)}}(ki)_{g^{(ij)}} = (ij)_{g^{(ij)}}.$$

Proposition now follows by induction on the length of permutations s, t. $\quad\square$

2.3. **An explicit presentation of $S_n(G)$.** In this section we obtain an explicit presentation of $S_n(G)$ similar in appearance to the presentation of parametrized braid groups from [6]. This presentation turns out to be much more economical than the original definition given in section 2.1. An explicit presentation for the subgroup $HS_n(G)$ is derived from this presentation via Reidemeister-Schreier method.

We start with the following simple lemma which is, in essence, a variant of the standard presentation of a Weyl group in terms of reflections with some redundant generators and relations added (cf. [3, Theorem 2.4.3]).

`lm:Snpres`	**Lemma 2.5.** *For $n \geq 3$ The symmetric group S_n admits presentation with transpositions as the set of generators and the following list of defining relations (in every formula distinct letters denote distinct indices):*

`{Sym1}`	(S1)	$$(ij)^2 = 1,$$
`{Sym2}`	(S2)	$$(ij)^{(jk)} = (ik),$$
`{Sym3}`	(S3)	$$[(ij),(kl)] = 1.$$
`{Sym0}`	(S4)	$$(ij) = (ji),$$

Now we are ready to formulate the main result of this subsection.

`prop:Q-pres`	**Proposition 2.6.** *For $n \geq 3$ and arbitrary group G the group $S_n(G)$ admits presentation with the set of generators $\{(ij)_a \mid i \neq j, 1 \leq i, j, \leq n, a \in G\}$ and the following list of relations (as before, distinct letters denote distinct indices):*

`{Q1}`	(SG1)	$$(ij)_a^2 = 1,$$
`{Q2}`	(SG2)	$$(ij)_a^{(jk)_b} = (ik)_{ab},$$
`{Q3}`	(SG3)	$$[(ij)_a, (kl)_b] = 1.$$
`{Q4}`	(SG4)	$$(ij)_a = (ji)_{a^{-1}}$$

Proof. Denote by S' the group from the statement of the proposition. For $1 \leq i \leq n$ and $x \in G$ denote by $x[i]$ the element of G^n whose only nontrivial component equals x and is located in the i-th position.

It is not hard to deduce from the definition of $S_n(G)$ and Lemma 2.4 that the formula $(ij)_a \mapsto (ij)_{a[j]}$ gives a well-defined map $\varphi \colon S' \to S_n(G)$.

Now we are going to construct the map $\psi \colon S_n(G) \to S'$ in the opposite direction. Using the presentation of S_n given by Lemma 2.5 we define for a fixed $g \in G^n$ the map $\psi_g \colon S_n \to S'$ by $\psi_g((ij)) = (ij)_{g_i^{-1}g_j}$. It is obvious that ψ_g preserves the defining relations (S1)–(S4) of S_n. It remains to show that the equation $\psi_g(s) = \psi_h(s)$ holds whenever $g, h \in G^n$ and $s \in S_n$ satisfy the requirement of (2.1).

Indeed, if hg^{-1} is fixed by s then for every $1 \leq i \leq n$ we have $(hg^{-1})_i = (hg^{-1})_{s(i)}$, or equivalently $h_i^{-1}h_{s(i)} = g_i^{-1}g_{s(i)}$. For example, if s is a cycle of length p, i.e.

$s = (i_1, i_2, \ldots i_p)$ with $i_{k+1} = s(i_k)$ we get that

$$\psi_g(s) = \psi_g \left(\prod_{k=1}^{p-1} (i_k, i_{k+1}) \right) = \prod_{k=1}^{p-1} (i_k, i_{k+1})_{g_{i_k}^{-1} g_{i_{k+1}}} = \prod_{k=1}^{p-1} (i_k, i_{k+1})_{h_{i_k}^{-1} h_{i_{k+1}}} = \psi_h(s).$$

The proof for a general s is almost the same. Verification of the fact that ψ and φ are mutually inverse is also immediate. $\qquad\square$

We now obtain a presentation of the subgroup $HS_n(G)$. For every $i \neq j$ and $a \in G$ we define the element $h_{ij}(a) \in HS_n(G)$ as follows:

{eq:h-def}　　(2.6)　　　　　　　　　　　$$h_{ij}(a) = (ij)_a \cdot (ij)_1.$$

It is not hard to show that $h_{ij}(a)$ form a generating set for $HS_n(G)$. In fact, there is an explicit formula how an element of $HS_n(G)$ originally expressed through $(ij)_a$'s can be rewritten in terms of $h_{ij}(a)$. Indeed, if h lies in $HS_n(G)$ and is written as $\prod_{k=1}^{N}(i_k j_k)_{a_k}$ for some $i_k \neq j_k$ and $a_k \in G$ then it can be rewritten as follows:

{eq:rp}　　(τ)　　　　　　$$h = \prod_{k=1}^{N} h_{\sigma_k(i_k), \sigma_k(j_k)}(a_k), \text{ where } \sigma_k = \prod_{s=1}^{k-1}(i_s j_s) \in S_n.$$

We briefly recall the notion of a *rewriting process* given in [7, § 2.3]. If G is a group presented by generators a_ν and relations $R_\mu(a_\nu)$ and H is its subgroup with a generating set $J_i(a_\nu)$ then a *rewriting process for H* is a function which maps every word u in alphabet a_ν to a word v in alphabet s_i such that u and $v[s_i := J_i]$ define the same element of G whenever u represents an element of H.

With this terminology, the mapping (τ) defined above is a rewriting process for the subgroup $HS_n(G)$. Since it does not arise as a rewriting process corresponding to a coset representative function, this process is *not* a Reidemeister rewriting process in the sense of [7, § 2.3]. However, it still satisfies the following two key properties of a Reidemeister rewriting process (cf. with (v) and (vi) of [7, § 2.3]):

- if U and U^* are freely equal words in $(ij)_a$ then $\tau(U)$ and $\tau(U^*)$ are also freely equal words in $h_{ij}(a)$;
- if U_1 and U_2 are two words in $(ij)_a$ which define elements of $HS_n(G)$ then the words $\tau(U_1 U_2)$ and $\tau(U_1)\tau(U_2)$ are equal.

Using these two properties and repeating the arguments used in the proof of [7, Theorem 2.8] one can simplify the generic presentation of $HS_n(G)$ given by [7, Theorem 2.6] and obtain the following.

lm:h-gen **Lemma 2.7.** *For $n \geq 3$ the group $HS_n(G)$ admits presentation on the generators $h_{ij}(a)$ with the following two families of defining relations:*

{eq:tau1} $$\text{(2.7)} \qquad\qquad h_{ij}(a) = \tau\left((ij)_a \cdot (ij)_1\right);$$

{eq:tau2} $$\text{(2.8)} \qquad\qquad \tau(KRK^{-1}) = 1,$$

where R varies over relations of Proposition 2.6 and K is any word in $(ij)_1$, $i \neq j$.

From (2.7) one immediately obtains the equality $h_{ij}(1) = 1$, $i \neq j$. Thus, if we denote by σ the permutation corresponding to a word K and let S_n act on $h_{ij}(a)$'s in the natural way we will get that the word $\tau(KRK^{-1})$ is equivalent to $^\sigma\tau(R)$ (modulo relations $h_{ij}(1) = 1$).

Since the relations from Proposition 2.6 are respected by the action of S_n, only relations of the form $\tau(R) = 1$ are, in fact, needed for the presentation of $HS_n(G)$. Writing down what $\tau(R)$ is for each of (SG1)–(SG4) we get the following.

prop:HSpres **Proposition 2.8.** *For $n \geq 3$ the group $HS_n(G)$ admits presentation with generators $h_{ij}(a)$ and the following list of relations:*

{H0} $$\text{(R0)} \qquad\qquad h_{ij}(1) = 1,$$

{H1} $$\text{(R1)} \qquad\qquad h_{ij}(a)h_{ji}(a) = 1,$$

{H2} $$\text{(R2)} \qquad\qquad h_{jk}(b)h_{ik}(a)h_{ij}(b) = h_{ik}(ab),$$

{H3} $$\text{(R3)} \qquad\qquad [h_{ij}(a), h_{kl}(b)] = 1,$$

{H4} $$\text{(R4)} \qquad\qquad h_{ij}(a)^{-1} = h_{ij}(a^{-1}).$$

3. Relationship with extensions of type $\mathfrak{H}_n(G)$

c:Hnextensions

We start by briefly reviewing the material of § 1–3 of [11]. Let $n \geq 3$ be a natural number. By definition, the group $H_n(G)$ is given by generators $h_{ij}(u)$, $u \in G$, $i \neq j$ and the following relations (cf. [11, H1–H5 of § 2]):

{RH1} $$\text{(H1)} \qquad\qquad h_{ij}(u)h_{ji}(u) = 1,$$

{RH2} $$\text{(H2)} \qquad\qquad h_{ij}(u)h_{ki}(u)h_{jk}(u) = 1,$$

{RH3} $$\text{(H3)} \qquad\qquad h_{ij}(u)h_{ik}(v)h_{ij}(u)^{-1} = h_{ik}(uv)h_{ik}(u)^{-1}, \qquad\qquad \text{for } j \neq k$$

{RH4} $$\text{(H4)} \qquad\qquad h_{ij}(u)h_{kj}(v)h_{ij}(u)^{-1} = h_{kj}(vu)h_{kj}(u)^{-1}, \qquad\qquad \text{for } i \neq k$$

{RH5} $$\text{(H5)} \qquad\qquad [h_{ij}(u), h_{kl}(v)] = 1.$$

There is a surjective group homomorphism $H_n(G) \twoheadrightarrow D_n(G)$ sending $h_{ij}(g)$ to $d_{ij}(g)$. Here $d_{ij}(g)$ stands for the element of G^n whose i-th component equals g, j-th component equals g^{-1} and all other components are trivial.

By definition, *an extension of type $\mathfrak{H}_n(G)$* is an extension H of $D_n(G)$ that is also a quotient of $H_n(G)$, i.e. the extension that fits into the following diagram.

$$H_n(G)$$
$$H \longrightarrow\!\!\!\!\!\rightarrow D_n(G)$$

Any $\mathfrak{H}_n(G)$-extension is central, see [11, Proposition 2.3].

We now recall the notion of *an extension of type $\mathfrak{U}(G)$* introduced by Rehmann in [11, § 1]. Let G be a group. Denote by $U(G)$ the group presented by generators (u,v), $u,v \in G$ and relations:

(U1) $$({}^u v, {}^u w)(u,w) = (uv,w),$$

(U2) $$(u,vw)(v,wu)(w,uv) = 1.$$

There is a left action of G on $U(G)$ given by ${}^x(u,v) = ({}^x u, {}^x v)$. Equivalently, $U(G)$ can be defined by the following relations, see [4, p. 8].

(3.1) $$(u,v)(v,u) = 1,$$

(3.2) $$(u,v)\ {}^v(u,w) = (u,vw),$$

(3.3) $${}^u(v,w)(w,v) = (u,[v,w]).$$

It is clear from the definition that $U(G)$ is a quotient of the nonabelian tensor square $G \otimes G$ and that the map $(u,v) \mapsto [u,v]$ defines a G-equivariant map $U(G) \twoheadrightarrow [G,G]$. Notice that in the literature one can find alternative notations for $U(G)$ which emphasize its connection with nonabelian tensor products e.g. (G,G) or $G \widetilde{\wedge} G$.

By definition, an *extension of type $\mathfrak{U}(G)$* is simply a quotient of $U(G)$ that fits into the following commutative diagram with G-equivariant arrows.

$$U(G)$$
$$U \longrightarrow\!\!\!\!\!\rightarrow [G,G]$$

There is a correspondence between extensions of type $\mathfrak{H}_n(G)$ and $\mathfrak{U}(G)$. One can obtain a $\mathfrak{U}(G)$-extension from given $\mathfrak{H}_n(G)$-extension via restriction. Indeed, let H be an extension of type $\mathfrak{H}_n(G)$ and k be arbitrary number $1 \leq k \leq n$. Denote by ι_k the inclusion map $[G,G] \to D_n(G)$ that inserts an element $g \in [G,G]$ at the k-th position. Then the corresponding extension U_H is simply the pull-back of H with respect to ι_k.

In other words, U_H is simply the subgroup of H generated by symbols $c_{kj}(u,v) = h_{kj}(u) \cdot h_{kj}(v) \cdot h_{kj}(vu)^{-1}$ (here j is any index not equal k, $c_{kj}(u,v)$ does not depend

on j, see [11, Proposition 2.1]). It can be shown that U is an extension of type $\mathfrak{U}(G)$ with kernel $\mathrm{Ker}(\pi_U)$ isomorphic to $\mathrm{Ker}(\pi_H)$, see [11, Propositions 2.2–2.3]. In [11, § 3] Rehmann also describes the inverse construction which assign to every $\mathfrak{U}(G)$-extension $U \twoheadrightarrow [G, G]$ and a number $n \geq 3$ some extension H_U of type $\mathfrak{H}_n(G)$ that fits into the pull-back diagram above.

3.1. **A simpler presentation of $H_n(G)$.** The aim of this subsection is to obtain a presentation of $H_n(G)$ that is simpler than the original presentation: 4 instead of 5 relations that are also shorter. Our main result is the following.

`prop:simpler`

Proposition 3.1. *For $n \geq 3$ relations* (R0)–(R4) *imply* (H1)–(H5). *Moreover, for $n \geq 4$ relations* (R0)–(R3) *are equivalent to* (H1)–(H5).

For $u, v \in G$ we define the following two symbols:
$$c_{ij}(u, v) = h_{ij}(u)h_{ij}(v)h_{ij}(vu)^{-1}, c'_{ij}(u, v) = h_{ij}(u)h_{ij}(v)h_{ij}(uv)^{-1}.$$

Notice that (H4) implies $h_{ij}(1) = 1$ therefore $c_{ij}(u, u^{-1}) = c'_{ij}(u, u^{-1})$. Our goal is to show that (H3) can be omitted from the definition of $H_n(G)$ provided $n \geq 4$.

`item-lem33`

Lemma 3.2. *If one excludes relation* (H3) *from the list of defining relations for the group $H_n(G)$, $n \geq 3$, the following still remain true:*

`item-lem33-cntr`
`item-lem33-comm`
`item-lem33-conj`
`item-lem33-conj2`

    (1) *The elements $c_{ij}(u, u^{-1})$ are central in $H_n(G)$;*
    (2) *One has $c'_{ij}(u, v) = [h_{ij}(u), h_{kj}(v)]$, $k \neq i, j$;*
    (3) *One has ${}^{h_{ij}(w)}c'_{kj}(u, v) = c'_{kj}(u, w)^{-1}c'_{kj}(u, vw)$, $k \neq i, j$;*
    (4) *One has ${}^{h_{ij}(w)}c'_{ij}(u, v) = c'_{ij}(uw, v)c'_{ij}(w, v)^{-1}$.*

Proof. First one shows using (H4) that $c_{ij}(u, u^{-1})$ centralizes $h_{kj}(v)$ (cf. with the proof of [11, Lemma 2.1(2)]). Since in any group $[a, b] = 1$ implies $[a^{-1}, b] = [a, b^{-1}] = [a^{-1}, b^{-1}] = 1$ we get that $c_{ij}(u, u^{-1})$ also centralizes $h_{kj}(v)^{-1} = h_{jk}(v)$ and $c_{ij}(u^{-1}, u)^{-1} = c_{ji}(u, u^{-1})$ centralizes both $h_{kj}(v)$ and $h_{jk}(v)$. Together with (H2) and (H5) this implies that $c_{ij}(u, u^{-1})$ centralizes all the generators of $H_n(G)$ and hence lies in the center of $H_n(G)$.

The second and third assertions are straightforward corollaries of (H4). The fourth assertion follows from the third one:
$${}^{h_{ij}(w)}c'_{ij}(u, v) = {}^{h_{ij}(w)}c'_{kj}(v, u)^{-1} = (c'_{kj}(v, w)^{-1}c'_{kj}(v, uw))^{-1} = c'_{ij}(uw, v)c'_{ij}(w, v)^{-1}.$$
$\square$

Lemma 3.3. *If one excludes relation* (H3) *from the list of defining relations for the group $H_n(G)$, $n \geq 3$, the following statements are equivalent:*

`item1`
`item4`

    (1) (H3) *holds;*
    (2) *one has $c'_{ij}(u, v)^{-1} = c'_{ij}(v, u)$;*

(3) symbols $c'_{ij}(u,v)$ do not depend on i;
(4) one has $c'_{ij}(u, vw) = c'_{ij}(wu, v) \cdot c'_{ij}(uv, w)$;
(5) one has $c'_{ij}(u, vu^{-1}) = c'_{ij}(uv, u^{-1})$.

Proof. Implications (1) $\implies$ (2) $\implies$ (3) $\implies$ (4) are essentially contained in the proof of [11, Lemmas 2.1-2.2]. Implication (4) $\implies$ (5) is trivial.

We now prove (5) $\implies$ (1). Notice that (H4) implies $^{h_{ij}(u)^{-1}}h_{ik}(v) = h_{ik}(u)^{-1}h_{ik}(vu)$, therefore using Lemma 3.2.(1) we get that $^{h_{ij}(u)}h_{ik}(v) = {}^{c_{ij}(u,u^{-1})h_{ij}(u^{-1})^{-1}}h_{ik}(v) = h_{ik}(u^{-1})^{-1}h_{ik}(vu^{-1})$. Thus, (H3) is equivalent to the equality

$$h_{ik}(uv)h_{ik}(u)^{-1} = h_{ik}(u^{-1})^{-1}h_{ik}(vu^{-1}),$$

or what is the same

$$c'_{ik}(u^{-1}, uv) = h_{ik}(u^{-1})h_{ik}(uv) = h_{ik}(vu^{-1})h_{ik}(u) = c'_{ik}(vu^{-1}, u).$$

It is clear that the last equality is an equivalent reformulation of (5). $\qquad\square$

Proof of Proposition 3.1. The assertion of the proposition becomes evident once one notices the following:

- (H2) and (H4) are implied by (R0)–(R2);
- (R0) follows from (H4);
- (R2) follows from (H1), (H2) and (H4);
- (H4) and (H3) are equivalent in the presence of (R4);
- for $n \geq 4$ the third statement of the previous lemma follows from Lemma 3.2.(2).

$\qquad\square$

Corollary 3.4. *For $n \geq 3$ the group $HS_n(G)$ is the quotient of the extension $H_n(G)$ by (R4) and, in particular, is an $\mathfrak{H}_n(G)$-extension. The associated $\mathfrak{U}(G)$ extension $U_{HS_n(G)}$ is isomophic to the quotient of $U(G)$ modulo single family of relations*

$$(u, u) = 1, \ u \in G.$$

In particular, we have the following natural isomorphism:

(3.4) $\qquad \mathrm{Ker}(HS_n(G) \to D_n(G)) = \mathrm{Ker}(S_n(G) \to G \wr S_n) \cong \mathrm{H}_2(G, \mathbb{Z}).$

Proof. Most of the assertions follow from Proposition 3.1 and [4, Proposition 5]. One also has to use the formula $c_{ij}(u, u) = c_{ij}(u, u^{-1})$ (see [11, p. 87]). $\qquad\square$

4. Topological applications

In this section we prove topological claims made in the introduction.

4.1. **Proof of main results.** Recall that for arbitrary set X one defines the space EX as the the simplicial set whose set of k-simplices EX_k is X^{k+1} and whose faces and degeneracies are obtained by omitting and repeating components. For a group G we denote by π_G the canonical map $EG \to BG$ sending $(g, h) \in EG_1$ to $g^{-1}h \in BG_1$.

Now let N be a group acting on X. We define two simplicial sets U and V as follows:

$$U = \bigcup_{n \in N} E(\Gamma_{n.-}) \subseteq E(X \times X), \quad V = \bigcup_{x,y \in X} E(N(x \to y)) \subseteq EN.$$

Here $\Gamma_{n.-}$ is the graph of the function $(x \mapsto nx)$ and $N(x \to y)$ denotes the subset of elements $n \in N$ satisfying $nx = y$. With this notation the subset $N(x \to x)$ coincides with the stabilizer subgroup $N_x \leq N$.

```
lm:quillen-a
```

Lemma 4.1. *The simplicial sets U and V are homotopy equivalent.*

Proof. First, we define yet another simplicial set W as follows. Its k-simplices W_k are matrices $\left(\begin{smallmatrix} x_0 & x_1 & \cdots & x_k \\ n_0 & n_1 & \cdots & n_k \end{smallmatrix} \right)$, where $x_i \in X$ are $n_i \in N$ are such that all n_i's act each x_j in the same way, i.e. $n_i x_j = n_{i'} x_j$ for $0 \leq i, i', j \leq k$. The faces and degeneracies of W are the maps of omission and repetition of columns.

Now there are two simplicial maps $f \colon W \to U$, $g \colon W \to V$ whose action on 0-simplicies is given by $f \left(\begin{smallmatrix} x_0 \\ n_0 \end{smallmatrix} \right) = (x_0, n_0 x_0)$, $g \left(\begin{smallmatrix} x_0 \\ n_0 \end{smallmatrix} \right) = n_0$. To prove the lemma it suffices to show that f and g are homotopy equivalences. The proof for f and g is similar, let us show, for example, that g is a homotopy equivalence.

In view of Quillen theorem A (cf.[13, ex. IV.3.11]) it suffices to show that for each p-simplex $d \colon \Delta^p \to V$ the pullback $g/(p, d)$ of d and g is contractible. The simplicial set $g/(p, d)$ can be interpreted as the subset of $\Delta^p \times E(X)$ whose set of k-simplices consists of pairs $(\alpha \colon \underline{k} \to \underline{p}, (x_0, \ldots, x_k) \in X(\alpha, d)^{k+1})$. Here $X(\alpha, d)$ is the subset of X consisting of all x for which $d_{\alpha(i)} x = d_{\alpha(j)} x$ for $0 \leq i, j \leq k$. Notice that the set $X_d := X(id_{\underline{p}}, d)$ is nonempty and is contained in every $X(\alpha, d)$ (it even equals $X(\alpha, d)$ for surjective α). Now choose a point $\widetilde{x} \in X_d$ and consider the simplicial homotopy

$$H \colon \Delta^p \times EX \times \Delta^1 \to \Delta^p \times EX$$

between the identity map of $\Delta^p \times EX$ and the map $\Delta^p \times c_{\widetilde{x}}$, where $c_{\widetilde{x}}$ is the constant map. More concretely, H sends each triple $(\alpha \colon \underline{k} \to \underline{p}, (x_0, \ldots, x_k), \beta \colon \underline{k} \to \underline{1})$ to $(\alpha, (x_0, \ldots, x_{i-1}, \widetilde{x}, \ldots, \widetilde{x}))$, where i is the minimal number such that $\beta(i) = 1$. By the choice of $\widetilde{x}$ the image of H restricted to $g/(p, d) \times \Delta^1$ is contained in $g/(p, d)$, hence $g/(p, d)$ is contractible. $\square$

Now suppose that $X = H$ is also a group upon which N acts on the left.

cor:ker-iso **Corollary 4.2.** *Consider the following two simplicial sets:*

$$S = \bigcup_{h \in H} BN_h \subseteq BN, \quad T = \pi_N(U) \subseteq B(H \times H).$$

There is an isomorphism $\mathrm{Ker}(\pi_1(S) \to N) \cong \mathrm{Ker}(\pi_1(T) \to H \times H)$. Moreover, the higher homotopy groups of S and T are isomorphic.

Proof. Consider the following two pull-back squares:

$$
\begin{array}{ccc}
V \hookrightarrow EN & \quad & U \hookrightarrow E(H \times H) \\
\downarrow \quad \downarrow \pi_N & \quad & \downarrow \quad\quad \downarrow \pi_{H \times H} \\
S \hookrightarrow BN & \quad & T \hookrightarrow B(H \times H)
\end{array}
$$

The required isomorphism can be obtained from the homotopy long exact sequence applied to the left arrows of these diagrams. □

Now let G be a group. Set $N = G \wr S_n$, $H = G^n$ and consider the left action of N on H given by $(g, s) \cdot h = gh^{s^{-1}}$, $g, h \in G^n$, $s \in S_n$. If one reorders the components of BG^{2n} accordingly, the simplicial subset $T \subset BG^{2n}$ from the above corollary becomes precisely the preimage of 0 under $h_n \colon BG^{2n} \to \mathbb{Z}[BG]$.

It is also easy to compute the map $\pi_1(S) \to N$. Indeed, van Kampen theorem [8, Theorem 2.7] asserts that $\pi_1(S)$ is isomorphic to the free product of stabilizer subgroups $N_h \leq N$ amalgamated over pairwise intersections $N_h \cap N_{h'}$, $h, h \in H$. For $h \in G^n$ the subgroup N_h consists of elements $(g, s) \in N$ satisfying $gh^{s^{-1}} = h$, i.e. elements of the form $(hh^{-s^{-1}}, s)$. Thus, $N_h \cong S_n$, $\pi_1(S)$ is isomorphic to the group $S_n(G)$ and the map $\pi_1(S) \to N$ coincides with the map μ defined in section 2.1.

ex44 **Example 4.3.** We leave it as an exercise to the reader to check that an element $[h_{12}(x), h_{13}(y)] \in \pi_1(S)$ corresponds to the following element of $\pi_1(T)$ under the isomorphism of Lemma 4.1:

{eq:pathT} (4.1) $\quad \gamma_{x,y} = (x[1], x[1]) \circ (x^{-1}[1], x^{-1}[2]) \circ (y[1], y[1]) \circ (y^{-1}[1], y^{-1}[3]) \circ$
$$\circ (x[1], x[2]) \circ (x^{-1}[1], x^{-1}[1]) \circ (y[1], y[3]) \circ (y^{-1}[1], y^{-1}[1])).$$

Proof of Theorem 2. Factor h_n as a composition of a trivial cofibration followed by a fibration:

{eq:fibr-repl} (4.2) $$BG^{2n} \hookrightarrow E_{h_n} \xrightarrow{ev_1 \circ \pi_2} \mathbb{Z}[BG]$$

For example, we can define E_{h_n} and the homotopy fiber F_{h_n} via the usual path space construction (here we use the fact that BG and $\mathbb{Z}[BG]$ are fibrant).

$$
\begin{array}{ccc}
E_{h_n} \xrightarrow{\;\pi_2\;} \mathbb{Z}[BG]^I & \qquad & F_{h_n} \xrightarrow{\;\;} E_{h_n} \\
\Big\downarrow{\scriptstyle \pi_1} \qquad \Big\downarrow{\scriptstyle ev_0} & & \Big\downarrow \qquad \Big\downarrow{\scriptstyle ev_1 \circ \pi_2} \\
BG^{2n} \xrightarrow{\;h_n\;} \mathbb{Z}[BG] & & pt \xrightarrow{\;0\;} \mathbb{Z}[BG]
\end{array}
$$

Now write down the starting portion of the long homotopy exact sequence of the fibration $E_{h_n} \twoheadrightarrow \mathbb{Z}[BG]$ and denote by K the kernel of the map $\nu\colon \pi_1(T) \to G^{2n}$ induced by the embedding $h_n^{-1}(0) = T \subseteq BG^{2n}$. We come to the following commutative diagram:

$$
\begin{array}{ccccccccc}
1 & \longrightarrow & K & \longrightarrow & \pi_1(T) & \xrightarrow{\;\nu\;} & G^{2n} & \longrightarrow & H_1(G,\mathbb{Z}) & \longrightarrow & 1 \\
& & \Big\downarrow{\scriptstyle \psi} & & \Big\downarrow{\scriptstyle \phi} & & \Big\downarrow{\scriptstyle \cong} & & \Big\| & & \\
1 & \longrightarrow & H_2(G,\mathbb{Z}) & \longrightarrow & \pi_1(F_{h_n}) & \longrightarrow & \pi_1(E_{h_n}) & \longrightarrow & H_1(G,\mathbb{Z}) & \longrightarrow & 1
\end{array}
$$

We already know by Corollaries 3.4 and 4.2 that K is naturally isomorphic to $H_2(G,\mathbb{Z})$ provided $n \geq 3$.

Let us show that ψ is an isomorphism. Assume for a moment that G is an abelian group. In this case a generator $x \wedge y$ of $H_2(G,\mathbb{Z})$ in Miller's presentation corresponds to the class of 2-cycle $c = (x,y) - (y,x)$ (cf. [9, (14), p. 582]), which, in turn, corresponds to the following normalized 2-cycle:

$$(4.3) \quad c' = c - s_0 d_0 c - s_1 d_1 c + s_1 d_0 = (x,y) - (y,x) - (x,0) + (y,0) + (0,x) - (0,y).$$

Since F_{h_n} and $\mathbb{Z}[BG]$ are fibrant, any element of $\pi_1(F_{h_n}, 0)$ can be represented with some 1-simplex $(\gamma, s) \in G^{2n} \times \mathbb{Z}[BG]_2$ satisfying $d_2(s) = h_n(\gamma)$, $d_0(s) = d_1(s) = 0$. It remains to find in F_{h_n} the 1-simplex homotopic to the path $\phi(\gamma_{x,y})$ (cf. Example 4.3).

We use the following inductive procedure. Let γ_0 be an initial segment of a path γ in T for which we have already found such simplex (g^0, s^0) in F_{h_n} and let $g \in T_1$ be the next chain link. Set $s_0 = \sum(a_j, b_j) \in \mathbb{Z}[BG]_2$, $t = h_n(g^0, g) = \sum_{i=1}^{2n}(-1)^i(g_i^0, g_i)$ and compute the filler for the 3-horn $(0, \; , s_0, t)$. Denote the 1-st face of this filler by s_1. It is clear that $(g^0 g, s_1)$ is the image of $\gamma^0 \circ g$ via ϕ. The concrete formula for s_1 can be chosen e. g. as follows:

$$s_1 = \sum_{i=1}^{2n}(g_i^0 + g_i, -g_i) - \sum_j(a_j + b_j, -b_j).$$

Applying the above recipe to the path $\gamma_{x,y}$ we get an expression equal to (4.3). This shows that ψ is the identity map for an abelian group G. Since ψ is natural in

G, by Lemma 4.4 below we get that ψ is an isomorphism for arbitrary G, therefore ϕ is also an isomorphism, as claimed. □

lm:endotr **Lemma 4.4.** *The only natural endotransformations of the second homology functor* $H_2(-, \mathbb{Z})\colon \mathbf{Groups} \to \mathbf{Ab}$ *are morphisms of multiplication by* $n \in \mathbb{Z}$.

Proof. Denote by η an endotransformation $H_2(-, \mathbb{Z}) \to H_2(-, \mathbb{Z})$. When restricted to the subcategory of free finitely-generated abelian groups $\mathbf{Add}(\mathbb{Z}) \subseteq \mathbf{Ab}$ the second homology functor coincides with the second exterior power functor $A \mapsto \wedge^2 A$.

Recall from [1, Theorem 6.13.12] that the category of quadratic functors is equivalent to the category of quadratic $\mathbb{Z}$-modules (see Definition 6.13.5 ibid.) The functor $A \mapsto \wedge^2 A$ is clearly quadratic and corresponds to the quadratic $\mathbb{Z}$-module $0 \to \mathbb{Z} \to 0$ under this equivalence. Thus, we get that η restricted to $\mathbf{Add}(\mathbb{Z})$ coincides with the the morphism of multiplication by $n \in \mathbb{Z}$.

Consider the group $\Gamma_k = \langle x_1, y_1, \ldots x_k, y_k \mid [x_1, y_1] \cdot \ldots \cdot [x_k, y_k] \rangle$ (the fundamental group of a sphere with k handles). It is clear that the abelianization map $\Gamma_k \to \mathbb{Z}^{2k}$ induces an injective map $H_2(\Gamma_k, \mathbb{Z}) \cong \mathbb{Z} \to \wedge^2 \mathbb{Z}^{2k}$. Consider the following diagrams.

$$
\begin{array}{ccc}
\mathbb{Z} \hookrightarrow \wedge^2 \mathbb{Z}^{2k} & \qquad & \mathbb{Z} \xrightarrow{\chi} H_2(G, \mathbb{Z}) \\
\eta_{\Gamma_k} \downarrow \qquad \downarrow n\cdot & \qquad & \eta_{\Gamma_k} \downarrow \qquad \downarrow \eta_G \\
\mathbb{Z} \hookrightarrow \wedge^2 \mathbb{Z}^{2k} & \qquad & \mathbb{Z} \xrightarrow{\chi} H_2(G, \mathbb{Z})
\end{array}
$$

From the left diagram it follows that η_{Γ_k} is also the morphism of multiplication by n. For every element $x \in H_2(G, \mathbb{Z})$ there exist an integer k and a map $\chi\colon \Gamma_k \to G$ sending the generator of $H_2(\Gamma_k, \mathbb{Z})$ to x. From the right square we conclude that $\eta_G(x) = nx$, as claimed. □

APPENDIX A. SIMPLICIAL DOLD—SERRE FIBRATIONS

The aim of this appendix is to show that the map $h_\infty\colon X^\infty \to \mathbb{Z}[X]$ is a quasifibration under suitable assumptions on X.

We start with the definition of the simplicial analogue of the so-called "Dold—Serre fibration", i.e. a map posessing "weak covering homotopy property" (also called "delayed homotopy lifting property"), cf. [12, § 1.4.4]. We show in Lemmas A.2 and A.4 that the map h_∞ has this lifting property and that every map with this property is a quasifibration.

df:dhlp **Definition A.1.** Let C be a subclass of cofibrations in the category of simplicial sets. We say that a map of simplicial sets $p\colon E \to B$ satisfies *weak homotopy covering*

property with respect to C if for every commutative square

`{eq:plp-def}` (A.1)

$$
\begin{array}{ccc}
U & \xrightarrow{\,g\,} & E \\
{\scriptstyle i}\downarrow & {\scriptstyle\widetilde{F}}\nearrow & \downarrow{\scriptstyle p} \\
V & \xrightarrow[\,F\,]{} & B
\end{array}
$$

for which $i \in C$ there exists a map $\widetilde{F}$ such that the lower triangle commutes strictly and the upper one commutes up to a fiberwise homotopy H (i. e. a homotopy H such that $pH \colon U \times I \to B$ coincides with the composite $U \times I \xrightarrow{\pi} U \xrightarrow{pg} B$).

Denote by C_{pr} the class consisting of all the inclusions $i \colon U \hookrightarrow V$ of finite polyhedral simplicial sets posessing a retract $r \colon V \to U$.

`lm:dhlp` **Lemma A.2.** *Let X be a fibrant connected simplicial set. The map $h_\infty \colon X^\infty \to \mathbb{Z}[X]$ satisfies the weak covering homotopy property with respect to the class C_{pr}.*

Proof. We reduce the original problem to the special case $g = 0$. Since U is finite the image of g is contained in $X^{2N} \subset X^\infty$. Assume that $\widetilde{F}_0$ is a lifting for the diagram (A.1) in which the top map equals 0 and the bottom is $F_0 = F - h_\infty gr$. For any maps $f \colon A \to X^\infty$ and $g \colon A \to X^{2N}$ one can define their product $g \times f$ by $(g \times f)(a) = (g(a); f(a)) \in X^\infty$. Clearly, then $\widetilde{F} = gr \times \widetilde{F}_0$ would be the desired lifting of F.

Now choose a contractible fibrant simplicial set W which maps surjectively onto X (e. g. take W to be the path space fibration). Since $p \colon W \twoheadrightarrow X$ is surjective, the associated map between free simplicial abelian groups is a Kan fibration and we can choose a lifting $\widetilde{F}$ in the following diagram

$$
\begin{array}{ccc}
U & \xrightarrow{\,0\,} & \mathbb{Z}[W] \\
{\scriptstyle i_0}\downarrow & {\scriptstyle\widetilde{F}}\nearrow & \downarrow \\
V & \xrightarrow[\,F\,]{} & \mathbb{Z}[X]
\end{array}
$$

By [10, Lemma 9.1] the map $\widetilde{F}$ can be lifted along h_W in such a way that the bottom triangle in following diagram commutes strictly.

$$
\begin{array}{ccc}
U & \xrightarrow{\,0\,} & W^\infty \\
{\scriptstyle i_0}\downarrow & {\scriptstyle G}\nearrow & \downarrow{\scriptstyle h_W} \\
V & \xrightarrow[\,\widetilde{F}\,]{} & \mathbb{Z}[W]
\end{array}
$$

Notice that the image of Gi_0 is contained in the fiber $h_W^{-1}(0)$. It is not hard to show that $h_W^{-1}(0)$ is contractible (the contracting homotopy for W^∞ can be restricted to $h_W^{-1}(0)$). We get that Gi_0 is fiberwise homotopic to 0 hence the composite map $V \xrightarrow{G} W^\infty \to X^\infty$ is the desired lifting of F. □

The assertions of the following lemma are straightforward and are given without proof.

Lemma A.3. *Let* $p\colon (E,e) \to (B,b)$ *be a map of based topological spaces. Let* $p^{-1}(b) \hookrightarrow F_p(b) \subseteq E \times_B B^I$ *be the inclusion map of the fiber of p into the homotopy fiber. Denote k-th relative homotopy group (or set) $\pi_k(F_p(b), p^{-1}(b), e))$ by G_k.*

(1) *Maps of triples* $(D^k, S^k, pt) \to (F_p(b), p^{-1}(b), e)$ *are in one-to-one correspondence with commuting diagrams of the form*

(A.2)
$$
\begin{array}{ccc}
D^k & \xrightarrow{a} & E \\
{\scriptstyle i_0}\downarrow & & \downarrow{\scriptstyle p} \\
D^k \times I \xrightarrow{\pi} (D^k \times I)/J & \xrightarrow{A} & B
\end{array}
$$

Here J denotes $(S^k \times I) \cup (D^k \times \{1\})$. In the sequel we denote such a diagram by (a, A).

(2) *Two diagrams (a_0, A_0) and (a_1, A_1) represent the same element of G_k iff there exists a family of maps (a_t, A_t) continously depending on $t \in [0,1]$ such that $pa_t = A_t i_0$ holds for all t (we call such family a homotopy of diagrams).*

(3) *If $A\pi$ lifts with respect to p then the element of G_k given by (a, A) is trivial.*

(4) *Let (a, A) be a diagram and a' be any other map fiberwise homotopic to a (i. e. homotopic via some H satisfying $pH(S^k \times I) = \{b\}$). Then there exists a map A' such that (a', A') is diagram homotopic to (a, A).*

(5) *The third assertion remains true if instead of the strict equality $\widetilde{A}i_0 = a$ we require $\widetilde{A}i_0$ and a to be fiberwise homotopic.*

Lemma A.4. *Let $p\colon E \to B$ be a map of simplicial sets satisfying the weak covering homotopy property with respect to the class C_{pr}. Then the geometric realization of p is a quasifibration, i. e. for every point $b \in B_0$ the inclusion $|p|^{-1}(b) \hookrightarrow F_{|p|}(b)$ is a weak equivalence.*

Proof. We want to prove that $\pi_k(F_{|p|}(b), |p|^{-1}(b))$ are all trivial for $k \geq 1$. Clearly, it suffices to show that for every diagram (a, A) of the form (A.2) the map $|p|$ has a lifting $\widetilde{A}$ satisfying the requirements of Lemma A.3.(5).

The idea of the proof is to approximate (a, A) with a homotopic pair of simplicial maps and then invoke the weak covering homotopy property. The key inredient in the proof below is the simplicial approximation theorem [5, Theorem 4.7]. For brevity

we denote the subdivision functor $\mathrm{sd}^m \, \mathrm{sd}_*(-)$ from its statement by $s^m(-)$ and the canonical natural transformation $s^m X \to X$ by δ^m. We proceed in a number of steps.

- Denote the restriction of a to S^k by a_0. Notice that the image of a_0 is contained in $|p^{-1}(b)|$. Using the approximation theorem we find a simplicial map $a_0' \colon s^m(S^k) \to p^{-1}(b)$ such that $a|\delta^m| \cong |a_0'|$.
- It is clear that there exists a map $a' \colon D^k \to |E|$ extending $|a_0'|$ and fiberwise homotopic to a.
- Invoking the approximation theorem once again (with the initial condition specified by $|a_0'|$) we find $q > m$ and $a'' \colon s^q(D_k) \to E$ such that $a'|\delta^q| \cong |a''|$ rel S^k.
- Using Lemma A.3.(4) we extend the (topological) homotopy $a \cong a' \cong a''$ to a homotopy of diagrams $(a, A) \cong (a'', A')$.
- Applying the approximation theorem to A' with the initial condition on the boundary $\partial(D_k \times I) = D^k \times \{0\} \cup J$ given by pa'' and $const_b$, respectively, we find an integer $r > q$ and a map $A'' \colon s^r(D_k \times I) \to B$ such that $A'|\delta^r| \cong |A''|$ rel $\partial(D_k \times I)$.

Thus, we have obtained the following commutative diagram of simplicial sets

$$
\begin{array}{ccc}
s^r(D^k) & \xrightarrow{\ a''\gamma^{r-q}\ } & E \\
{\scriptstyle s^r(i)}\Big\downarrow & \nearrow\ \ \ \Big\downarrow {\scriptstyle p} \\
& \widetilde{A} & \\
s^r(D^k \times I) & \xrightarrow[\ A''\ ]{} & B
\end{array}
$$

By the functoriality of simplicial approximation the map $s^r(i)$ has a retract hence by our assumption there exists the desired lifting $\widetilde{A}$. $\square$
